### 3. Function Description

#### 3.1 Interface definition

### 3.1.1 Specification

The specification of power supply circuit and pins connection are shown as following table:

#### 3.1.1.1 Adoptability of Capacitor and PCB layout resistance.

Pins connection	Recommended voltage	Capacity	Resistance of wire ( $\Omega$ )
C11P/N, C12P/N, DDVDH	10V	1 $\mu$ F	< 10
VGAM1OUT	10V	1 $\mu$ F	< 15
C21P/N, C22P/N	10V	1 $\mu$ F	< 10
HVO, LVO	16V	1 $\mu$ F	< 10
VGH, VGL, ARREF	16V	1 $\mu$ F	< 15

**Table 5.1**

### 3.1.2 Connector

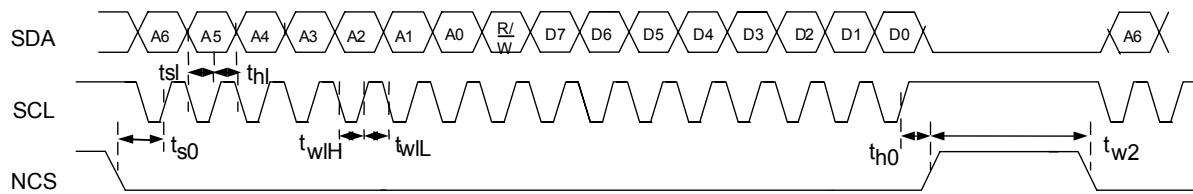

We use connector HRS FH26-71S-0.3SHW.

### 3.2 Serial Interface

The HX5116-A offers 3-wire serial interface to display initialization setting and to selecting display function.

The clock synchronized serial peripheral interface (SPI) using the chip select line (NCS), serial transfer clock line (SCL), serial input /output data (SDA). The SPI read or write is decision by R/W bit. If the R/W control bit is high, the data byte D7~D0 will be read from HX5116-A. If it is low, the data byte D7~D0 will be a write to HX5116-A. The HX5116-A starts serial data transfer at the falling edge of NCS input and it ends serial data transfer at the rising edge of NCS input. In serial bus interface, the data is transferred with the MSB first. On write mode, it needs to input 16 valid data to SPA. Under 16 or over 16 data, HX5116-A will judge as invalid data and ignore this command.

#### 3.2.1 Connector wire SPI Timing

#### 3.2.2 SPI timing diagram

Parameter	Symbol	Min.	Typ.	Max.	Unit
Time from NCS to SCL	Ts0	40	-	-	ns

### 3.3 Data Interface

The HX5116-A supports 8-bit serial RGB, 24-bit parallel RGB. For digital RGB input data format, both SYNC mode and DE mode are supported. When DE mode selected, display operations is executed in synchronization with the frame-synchronizing signal (VSYNC), line synchronizing signal (HSYNC) and dot clock (DCLK). The display data are transferred in pixel unit via Data bus(D27~D20、D17~D10、D07~D00) and according to the signal of data enable(DE). When SYNC mode is selected, display operation is executed in synchronization with only VSYNC, HSYNC and DCLK.

## 6. Reset Circuit

This block is integrated into the Interface Logic that includes Power on Reset circuitry and the hardware reset pin, NRESET. Both of these having the same reset function. Once the NRESET pin receives a negative reset pulse, all internal circuitry will start to initialize and output pin will normal operating after the next VSYNC falling edge. The NRESET minimum pulse width for completing the reset sequence is 10us.

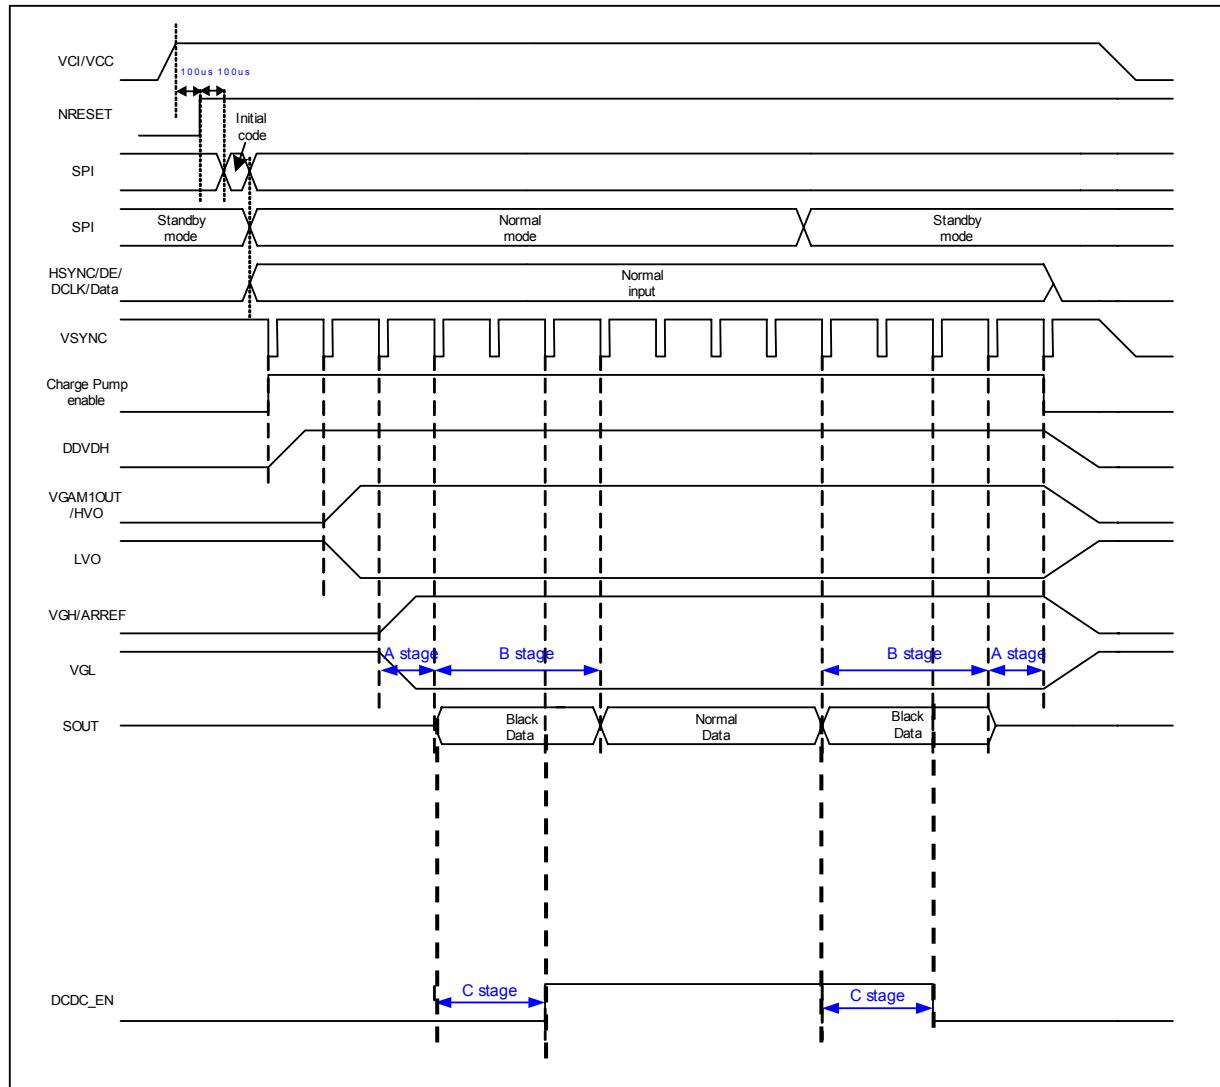

## 7. Power on/off Sequence

When power on/off HX116-A, please follow the sequence:

Power ON: VCI/VCC -> NRESET -> Normal mode

Power OFF: Standby mode -> wait A+B stage -> power off VCI/VCC
